

Evaluating Vegetation Modelling in Earth System
Models with Machine Learning Approaches
(Supplementary Figures for submission to the
Journal of Advances in Modeling Earth Systems
(JAMES))

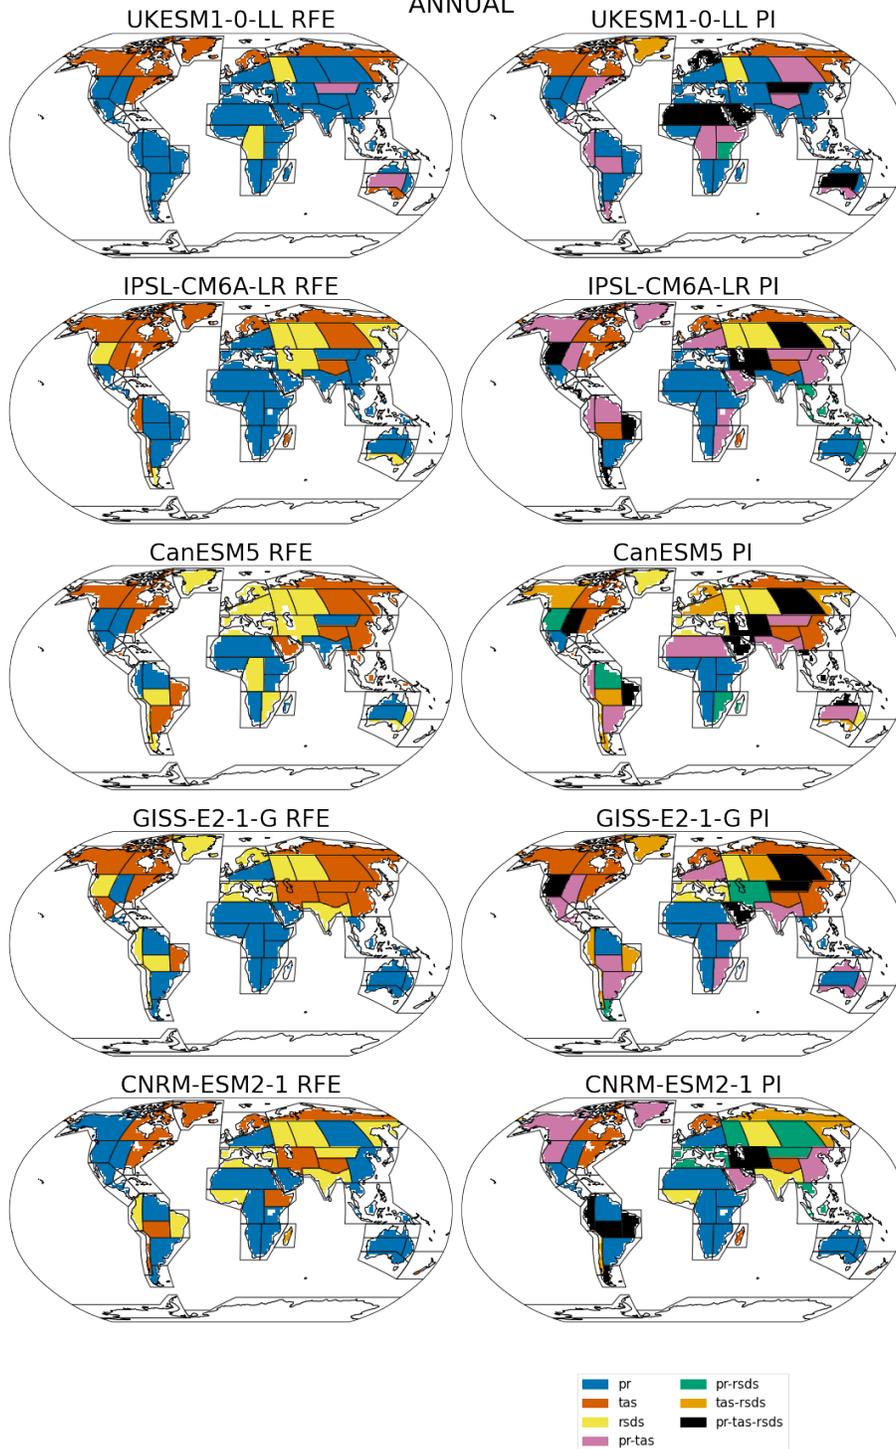

Ranjini Swaminathan Tristan Quaife Richard Allan

S1: Gross Primary Productivity values estimate by the ML emulator for a selection of IPCC regions. Every column shows the difference between the ML emulator output and the GPP simulated by a given ESM. The RMSE error is shown at the top of each region along with the difference in area averaged mean between the ML emulator estimates and the ESM simulated values. All units are in $\text{g}/\text{m}^2/\text{month}$.

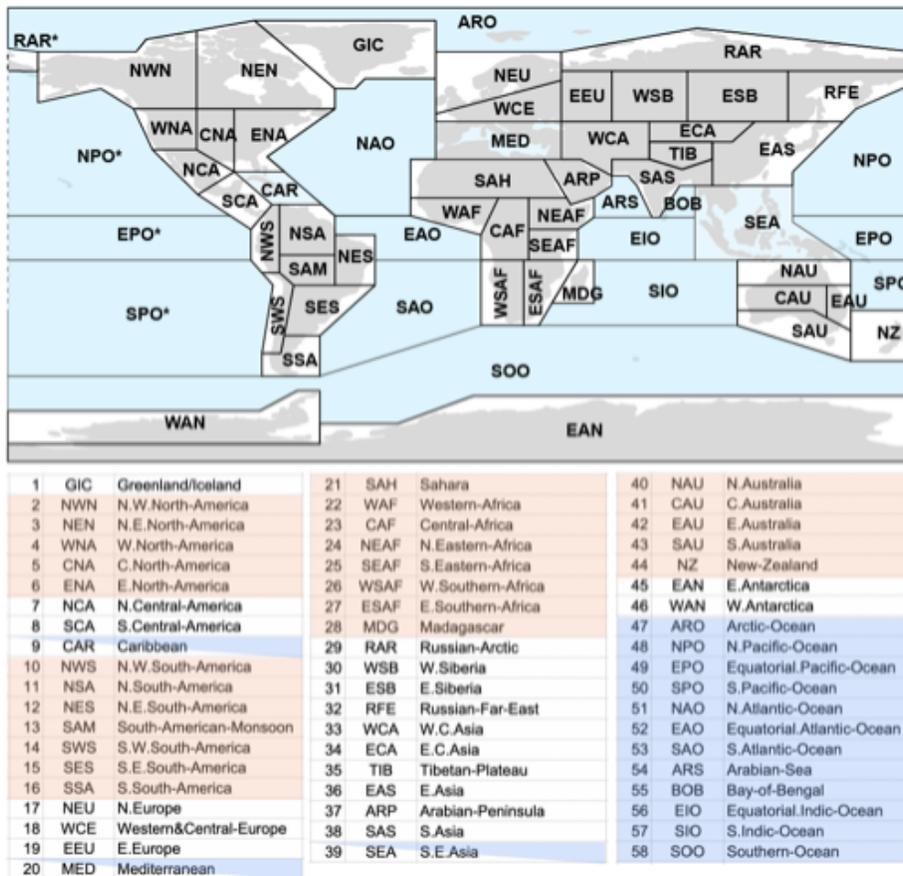

Regional Feature Importances

ANNUAL

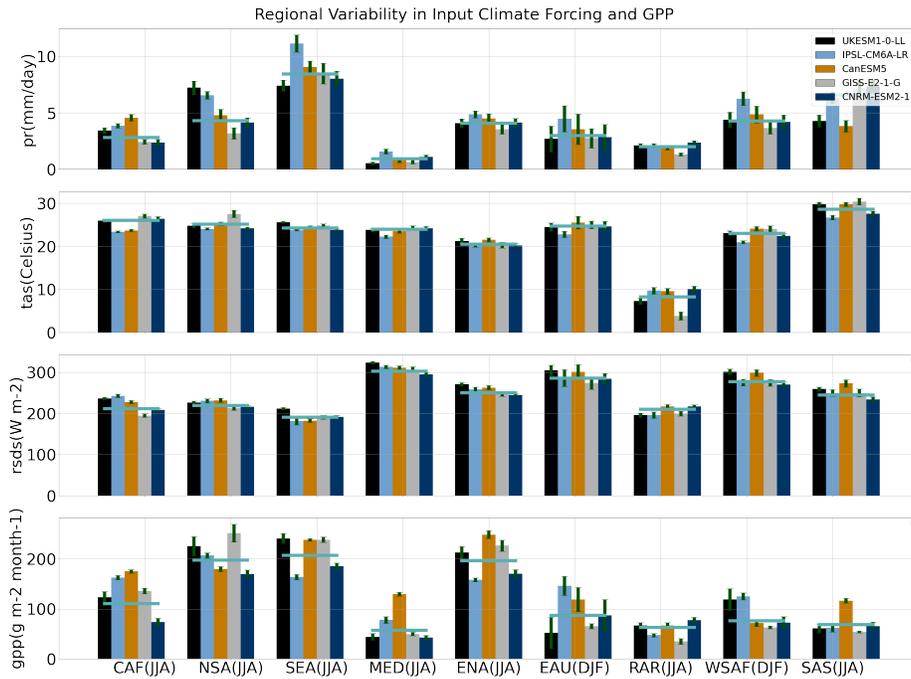

3

S2: Annual feature importance from two methods - Recursive Feature elimination and Permutation Invariance for IPCC regions.

S3: IPCC AR 6 reference regions and their acronyms.

S4: A comparison of means and standard deviations of the climate variables or input forcings considered important for GPP. Each row shows the mean and standard deviation for a single variable with colored bars representing individual models grouped by regions. Vertical lines overlaid on the colored bars shows the standard deviation and the horizontal line shows the multimodel mean.
